Abstract

Acute ischemic proctitis is an extremely rare clinical entity. It occurs most often in hemodynamic instability in patients with atherosclerosis and those with cardiovascular risk factors. Many patients will need proctectomy as a definitive treatment, especially for gangrenous proctitis. We present the case of acute ischemic proctitis in a 54-year-old man who had valvular disease and who fully recovered with conservative management. We also review the literature on ischemic proctitis.

Keywords: Ischemic proctitis • Rectum • Conservative management

Introduction

Ischemic proctitis is a rare emergency because the rectum is very well vascularized [1,2]. As in ischemic colitis, a spectrum of severity exists and ranges from superficial ischemia to total necrosis and perforation. Early recognition of this entity is of vital importance to avoid complications [3].

In this article, we present the case of ischemic proctitis in a 45-year-old man and we review the literature of this nosological entity.

Case Study

A 54-year-old man presented to the hospital with low-abundance rectal bleeding for 5 days associated with moderate proctalgia without fever. He had no similar episode in the past or notion of recent travel. He had mitral valve stenosis with tricuspid insufficiency on acoenocoumarol 2 mg/d. He also had arterial hypertension on ramipril 5 mg/d and asthma under symptomatic treatment.

On admission, his temperature was 37.1 °C, blood pressure 150/91 mm Hg, heart rate 92 beats per minute, and oxygen saturation 98% in ambient air. His abdominal exam revealed a non-distended abdomen that was tender only in his suprapubic region without peritoneal signs. The digital rectal examination was painful and the finger cot was stained with blood.

An initial blood test revealed normal white blood cell count (8,320/mm3), hemoglobin level of 14.7 g/dL with a hematocrit of 44% and platelets at 263,000/mm3. The C-reactive protein was 4.3 mg/L, the prothrombin level was 16.3% and the INR was 4.23. The remainder of his blood work was within normal limits.

Colonoscopy revealed an erythematous and edematous mucosa of the lower and middle rectum evolving in one piece with a clear limit of the remainder of the mucosa which appears normal (Figure 1). Abdomino-pelvic CT angiography revealed parietal thickening of the middle and lower rectum with target enhancement after injection of contrast. He also showed atheromatous calcifications of the abdominal infra-renal aorta and its primary iliac dividing branches (Figure 2). Histological examination of the rectal biopsies confirmed the diagnosis of ischemic proctitis.

Our patient started oral antibiotic treatment with Metronidazol 1500 mg/day for 7 days with rehydration. He also benefited from a cardiology consultation with therapeutic adjustment.

The course was marked by the disappearance of clinical symptoms from the tenth day. A follow-up colonoscopy performed on the 14th day revealed a normal-looking rectal mucosa (Figure 3). The patient is always followed regularly in consultation.

Discussion

Ischemic proctitis is a rare entity due to the rich vascularization of the rectum. It is estimated at 2% for pure rectal locations and 10% for lesions associated with the sigmoid [1,4]. Ischemic proctitis can be caused by acute vascular obstruction (usually after aortic surgery or radiologic intervention), severe vascular disease, or a low flow condition [4,5,6]. Other causes include radiation therapy, vasculitis, and myointimal hyperplasia of the mesenteric vein [7,8]. It often occurs in elderly patients during significant hemodynamic disturbances (aortic surgery, hypovolemic shock).

The clinical presentation is often severe with a risk of progression to gangrene during the acute phase and then to chronic forms (stenosis, ulcerations) [1,4]. The clinical symptoms of patients with ischemic proctitis are often nonspecific and misleading. Patients often present with lower abdominal pain, diarrhea with rectal bleeding and proctalgia. These presentations are nonspecific and are frequently seen in inflammatory bowel disease, pseudomembranous colitis or even colorectal tumor. Therefore, the distinction between these pathological entities is sometimes difficult [9-11].

The diagnosis must be suggested by CT scan in the presence of segmental, circumferential and symmetrical wall thickening of the rectal wall in favor of submucosal edema, with “target” enhancement of the wall after injection indicating an acute process [12]. Fat infiltration and poor peritoneal fluid effusion are possible [13].

Colonoscopy is the test of choice for the diagnosis of ischemic proctitis. It allows visualization of mucosal lesions; to assess the severity and extent and performance of biopsies [14]. It should be done with caution, without excessive insufflation [15]. The segmental character is suggestive of an ischemic origin. The lesions are clearly defined and rapidly evolving. As in ischemic colitis, a spectrum of severity exists and ranges from superficial mucosal ischemia to necrosis with perforation. Three endoscopic stages are described: stage 1: edema and erythema of the mucosa, stage 2: non-necrotic ulcerations, with an edematous mucosa, stage 3: extensive necrosis with gray-black appearance of the colon [16].

The therapeutic management of ischemic proctitis depends on its etiology and the severity of the clinical presentation and endoscopy results [14]. Early restoration of blood volume and optimization of cardiac flow is essential. Conservative management is the rule for the majority of cases with non-severe ischemic proctitis [2]. Broad-spectrum antibiotics may be prescribed [1,17]. The presence of gangrenous proctitis or perforation requires urgent surgery and in most cases complete proctectomy is necessary [18].

Conclusion

Ischemic proctitis is a rare entity. It should be considered in elderly patients with cardiovascular risk factors who present with low gastrointestinal manifestations. Conservative management should be favored in cases of superficial proctitis. Emergency surgery is the rule in cases of gangrenous proctitis.
